Network Guidelines for Pelvic Fractures
with or without Urogenital Trauma in Children

This Guideline is in accordance with the National Trauma Quality Indicators
ODN T16-1C-107  TU T16-2B-311  Paediatric MTC T16-2B-214
This document has been developed in response to the National Major Trauma Quality Indicators 2016 which require all Major Trauma ODNs, MTCs and TUs to develop, agree and put in place a Network Guideline for Pelvic Fracture Management in Adults with or without Urethral Injury.

All relevant staff should ensure they are fully aware of, and operate in line with this guideline.

Sheffield Children’s NHSFT Paediatric MTC Trauma Lead

Please note that from Jun 2017 all ODN Clinical Guidelines, Protocols and Policies will be available on the ODN website for downloading.
Management of Pelvic Fractures
With or Without Urogenital Trauma in Children

BACKGROUND

Pelvic fractures are rare in children, isolated pubic ramus fractures aside. Major disruption of the bony pelvic ring is very rare. There are many reasons for this. Paediatric TARN data support the fact that injuries to the pelvic region are rarer than cardio-thoracic or cervical spine injuries, which themselves are both very uncommon.

Urogenital trauma in association with the above type of major pelvic fracture is understandably also very rare.

It is highly unlikely that any trauma unit will receive a child with a fracture involving the pelvis, other than trivial avulsion fractures.

This guidance is for reference only and is adapted from the guidance on these injuries currently in use at Sheffield Children’s Hospital MTC and developed by their Lead Clinician for Trauma, Mr Chris FitzSimmons.

This guidance is due to be reviewed at the MTC in June 2018

If for whatever the reason a TU received a child with type of injury, he / she should be managed according to the principles of ATLS / APLS, stabilised, optimised for transfer, discussed with the team at Sheffield Children MTC and transfer arranged as soon as safe and possible.

The transfer is likely to involve EMBRACE and if so they must be contacted by the trauma team leader or the Paediatrician attending as part of the trauma team as soon as practicable.

KEY MANAGEMENT POINTS

1. During the initial exploratory survey / secondary survey,
   a) The external urethral meatus and the transurethral bladder catheter (if already inserted) should be examined for blood.
   b) The flanks, abdomen, perineum, and external genitals should be inspected for hematomas, ecchymosis, and external injuries.
   c) All patients with haematuria, bloody discharge from the urethral meatus, dysuria, inability to pass a catheter or suspicious features in the history (local hematoma, concomitant injuries, mechanism of injury) have an increased risk of genitourinary injuries and should be given a focused diagnostic evaluation of the kidney and/or the efferent urinary tract.

2. A single gentle attempt of passing a standard transurethral bladder catheter can be attempted by an experienced doctor, even if the clinical or CT findings suggest a urethral injury.
   a) An age appropriate soft silicone catheter and sterile technique should be used (standard of 16F size for children 14-16 years of age).
   b) If the catheter passes and clear urine comes through, then inflate the balloon.
c) If the catheter passes but blood stained urine comes through, then again inflate the balloon and perform a **catheter cystogram**. If the catheter will not pass or passes and frank blood is drained then DO NOT inflate the balloon, withdraw the catheter and perform a **retrograde urethrogram**.

d) If the insertion of standard transurethral bladder catheter fails, a **retrograde urethrogram** and the insertion of a **suprapubic catheter (SPC)** should follow.

3 In the case of circulatory instability that does not permit initial continuing diagnostic tests, and if it is impossible to insert a transurethral bladder catheter, a **percutaneous suprapubic urinary catheter** should be performed (with ultrasound guidance if necessary) or by laparotomy (with simultaneous exploration). See below for further guidance on **SPC**.

4 **Further imaging diagnostic tests** should be carried out on the efferent urinary tract if one or more of the following criteria apply:

   - haematuria
   - bleeding from the urethral meatus or vagina
   - dysuria
   - local hematoma

5 **Computed tomography with contrast agent** should be performed in the case of suspected kidney injury.

6 **CT cystogram** should be performed at the time of the initial trauma scan, when there is pelvic fracture or haematuria, if the patient is stable. If not stable, then **delayed cystogram either fluoroscopic or CT** should be performed.

7 When prioritizing permits, **retrograde urethrogram** and a **cystogram** should be performed in patients with clinical reference points for a urethral lesion.

8 When prioritizing permits, a **retrograde cystogram** should be performed in patients with clinical reference points for a bladder injury.

9 If there is an identified Bladder or Urethral injury, contact the **on-call Consultant Paediatric Surgeon**.

10 Extra-peritoneal bladder ruptures without involvement of the neck of the bladder can usually be conservatively treated through urethral urinary diversion, providing that there is no concurrent urethral injury. Intra-peritoneal bladder ruptures should be surgically explored.

11 Complete ruptures of the urethra should be treated in the emergency surgery phase by suprapubic urinary diversion with a view to undertaking delayed urethral reconstruction.

**RETROGRADE CONTRAST URETHROGRAM – CYSTOGRAM**

1 Always consult with the **Consultant Paediatric Surgeon in the MTC** prior to any investigation. It is rare that retrograde contrast studies will be done or be necessary in the paediatric population.

2 Discuss with **Radiology Consultant/Registrar**

3 Sterile technique must be used and the procedure performed by an experienced clinician.

4 If clear urine drains following catheterisation no further imaging is required. If there is any element of blood staining in the fluid draining from the catheter then a contrast study (**retrograde cystogram**) is mandated.
Retrograde Urethrogram:

- Usually in the Resuscitation room, Radiology suite, or in Theatres.
- An x-ray plate is needed under the pelvis.
- Use 20-50ml diluted (50% saline, 50% contrast) IV contrast medium in a bladder syringe.
- Insert an appropriate sized Foley catheter so that balloon is just past the meatus then gently inflate
  - balloon with 5mls saline.
- Hold in place whilst assistant injects contrast into catheter and take AP pelvis x-ray – if possible get an additional lateral film.

A Retrograde Urethrogram positive: call Consultant Paediatric Urologist. Decisions are now very difficult. If a suprapubic catheter is needed suggest discussion with the Orthopaedic surgeons, as this will have major implications for any internal fixation.

B Retrograde urethrogram negative: Catheterise. If haematuria perform retrograde cystogram.

Retrograde catheter cystogram:

- Usually in the Resuscitation room, Radiology suite, or in Theatres.
- An x-ray plate is needed under the pelvis.
- Push catheter in 2-3 cm so balloon is not blocking bladder neck.
- Inject 100-300ml diluted (50% saline, 50% contrast) IV contrast medium into the catheter.
- Clamp catheter.
- Take an AP pelvis x-ray (or CT if the patient is having one, or an additional Lateral x-ray if feasible).
- Evacuate the contrast and repeat imaging.

Suprapubic catheter

If a urethral catheter cannot be passed, a suprapubic catheter is required. This can be inserted during emergency laparotomy, but otherwise a percutaneous suprapubic catheter should be placed.

The suprapubic catheter should be placed using a Seldinger technique under ultrasound control by a doctor experienced in the use of USS guided SPC techniques.

- The skin insertion point MUST be in the midline (through the linea alba) and should be as high as is safely possible (without causing bowel damage) to prevent getting in the way of future surgery.
- A 14-16F silicone catheter should be used. This is large enough to allow blood clots to pass and avoid clot retention.
- If the bladder cannot be identified on USS and so a percutaneous suprapubic catheter cannot be placed, this is a very difficult situation. Consultant decision makers in Urology and Paediatric Surgery must be involved and open placement of the catheter +/- laparotomy should be considered.
- Urine becomes contaminated with bacteria within 5 hours of passage of a urinary catheter.
- If there is a urine leak from either the bladder or urethra, the pelvic fracture should be treated like an open long-bone fracture with antibiotics (Co-Amoxiclav + Gentamicin for 72 hours - seek microbiological advice if penicillin allergy) and early fracture fixation if the patient’s physiology allows.
Suprapubic catheters can be repositioned and tunnelled at the time of pelvic fracture fixation, but it is essential that they remain in the midline and at least 4-6cm above the symphysis as this allows the urologist access for the delayed urethral reconstruction.

**Bladder Injury**

- **Intraperitoneal Bladder Rupture** requires emergency laparotomy and direct repair. Thus, immediate referral to on-call PSU team, and discussion between on-call consultants – ED, PSU and Urology should follow such a diagnosis.

- **Extraperitoneal Bladder Rupture** may be treated by catheter drainage alone. However, in the presence of a pelvic fracture that requires fixation, fracture reduction and fixation along with primary repair of the bladder is recommended.

- Bladder injuries identified during pelvic fracture surgery should be repaired at the same time and bladder drainage (via urethral or suprapubic catheter, as appropriate) ensured. The PSU on-call team should be involved, so that appropriate treatment and follow up can be arranged.

- If the Bladder is repaired and the surgeon elects to insert a drain, this should not be a suction drain and it should probably be removed the next day.

- The prophylactic antibiotics commonly used for fracture surgery will also cover bacteria that commonly cause UTI. Prolonged or additional antibiotic cover would not usually be required.

- Earlier fracture surgery, when a suprapubic catheter is in place, is likely to reduce infection rates.

**Urethral repair**

- The indications for **Primary Urethral Repair** (within 48 hours) do not generally apply to children and are largely aimed at adults:

  - Associated ano-rectal injury
  - Perineal degloving
  - Massive bladder displacement
  - Penetrating trauma to the anterior urethra

**Delayed Primary Urethral Repair** (between 2 and 14 days) is usually indicated in children.

- All urethral injuries in children must be discussed at a very early stage with the appropriate supra-regional specialist in Paediatric Urology at SCH.

- The recommended definitive treatment for urethral rupture is **Delayed Repair** at 3 months post injury by a Paediatric Urologist with experience in this complex procedure.
